CHROMOSOME NUMBERS IN ANGIOSPERMS II

Bibliographia Genetica VI, 1930

ERRATA

Page 189 — In connection with *Melandrium alba* see also references for
Lychnis alba MILL. (GAISER 1926).

" 204 — Insert *Capparis spinosa* L.: $2n = 38$; KUHN, 1928b.

" 225 — *Rubus thyrsiger* BAB.; $n = 5 + 4_1$.

" 235 — Insert for *Prunus triloba* LDL.; $2n = 64$; KOBEL, 1927, instead of
DARLINGTON 1928.

" 236 — All the numbers for *Prunus avium* varieties should be under the
 $2n$ column instead of the n column.

Pages 236, 237, 240, 241, 244, 245 and 246 — Where CRANE 1927 is given, the
name is intended as a bibliographic reference. The counts were
made by DARLINGTON and given by CRANE 1927.

Page 344 — *Tripsacum Barberi* JESW. Should be *Saccharum Barberi* JESW.

" 345 — *Kassoer* not *Kassover*.

Pages 358—366 — Omit references to BLEIER 1926.

Page 455 — SKALINKA and CUCHTMAN should be 1927 instead of 1926.

CHROMOSOME NUMBERS IN ANGIOSPERMS III

BY

L. O. GAISER

As stated in the previous publication (GAISER 1930) lists of chromosome numbers were to be prepared annually to supplement those of the two previous lists (1926, 1930). The latter include investigations up to the end of 1928. The present includes the results of researches published during 1929 as well as some of 1928 which had not been received in time for the earlier papers.

The same method of arrangement as had been used previously has been followed here so that there may be as much uniformity as possible. Other annual supplemental lists will follow regularly in this same publication.

¹⁾ An unequal pair of chromosomes was distinguishable in meiotic divisions of the male flowers.

²⁾ Frequently a quadrivalent resulted from the fusion of 2 bivalents or a trivalent from the fusion of a bivalent and a univalent.

The somatic number was judged, by meiotic conditions, to be 82—84.

³⁾ A form of *S. sachalinensis* from Hokkaido had ca. 24 chromosomes and showed irregular divisions.

FAGACEAE			
<i>Fagus silvatica</i> L.		22	WETZEL, 1929.

¹⁾ Meiosis normal.²⁾ Meiosis very abnormal with varying numbers of bivalents and univalents.³⁾ Meiosis very abnormal.⁴⁾ At metaphase 10 chromosomes were in a ring and 4 were within the ring.⁵⁾ Meiosis was normal.⁶⁾ WOODWORTH (1929b) found 28 chromosomes in the embryo-sac initial where no reduction followed. Parthenogenesis and polyembryony resulted. WOODWORTH (1929c) reported meiosis extremely abnormal.

URTICALES

MORACEAE

<i>Morus bombycina</i> KOIDZ. . . .	14 ²⁾	SINOTO, 1929b.
<i>Cudrania triloba</i> HANCE . . .	28 ³⁾	" "
<i>Humulus japonicus</i>	8, 9 ⁴⁾	16, 17 WINGE, 1929; KIHARA, 1929a.

¹⁾ There were present lagging chromosomes, supernumerary cells in the pollen tetrad and micro pollen grains, but to a less degree than in distinct intermediate forms between *Q. sessiliiflora* × *Q. robur*.

²⁾ An unequal pair of chromosomes and also a large geminus which occasionally divided into two unequal parts were distinguishable in the meiotic divisions of male flowers.

³⁾ An unequal pair of chromosomes was distinguishable in the meiotic divisions of male flowers.

⁴⁾ According to WINGE (1929) the complex is represented by ♀ 2n = 14 + 24; ♂ 2n = 14 + 3x; ♀ n = 7 + x; ♂ n = 7 + x or 7 + 2x. According to KIHARA (1929a) the sex chromosomes form a tripartite complex of x, y, and y₂, so that ♀ 2n = 14 + 2x; ♂ 2n = 14 + y₁ + x + y₂; ♀ n = 7 + x; ♂ n = 7 + y₁ + y₂. SINOTO (1929b) confirmed KIHARA's observations.

<i>Reynoutria sachalinensis</i> NAKAI	22		SINOTO, 1929b.

¹⁾ In diakinesis an XY pair of chromosomes was found.²⁾ Tetraploid cells were found with 32 or 34 chromosomes.³⁾ See foot-note 4 page 166.⁴⁾ According to WINGE (1929) the complex is represented by ♀ 2n = 18 + 2x; ♂ 2n = 18 + x + y; ♀ n = 9 + x; ♂ n = 9 + x or 9 + y.⁵⁾ The tetrapartite chromosome found along with 8 bivalents was considered to be the pair of sex chromosomes; therefore, ♀ n = 8 + x₁ + x₂; ♂ n = 8 + x₁ + x₂ or 8 + y₁ + y₂ (SINOTO, 1929a and b).⁶⁾ At metaphase of meiosis of the male flowers there were 6 bivalent + 1 tetrapartite chromosome, and at anaphase 7 and 8 chromosomes, respectively. In female plants there were 14 somatic chromosomes and in male plants 15, so ♀ 2n = 12 + 2M; ♂ 2n = 12 + m₁ + M + m₂; ♀ n = 6 + M; ♂ n = 6 + M or 6 + m₁ + m₂.⁷⁾ 14 chromosomes were found in an embryo-sac-mother-cell.

¹⁾ In first division metaphase 27 scattered unpaired chromosomes were seen but in the second division anaphase 62—74 chromosomes were counted.

²⁾ In second division anaphase though there might be 2—5 lagging chromosomes on the spindle, they passed undivided to the poles.

„ <i>usitatissimum</i> L. ⁵⁾ . .	15	30-32	SIMONET, 1929e.

ERYTHROXYLACEAE

<i>Erythroxylum Coca</i>	24	HEITZ, 1929a.
<i>Xanthoxylum piperitum</i> DC. .	35 ⁶⁾	SINOTO, 1929b.

¹⁾ In some cases the 14 chromosomes were arranged as 5 double chromosomes on the equatorial plate, 4 chromosomes having joined to form one large ring.

²⁾ In heterotypic division the chromosomes were arranged as a ring of 4 + 5 pairs.

³⁾ Two different strains, one a low herb and the second a larger form, showed the same number of chromosomes.

⁴⁾ 4 lots of this species were examined.

⁵⁾ 35 varieties of this species were examined.

⁶⁾ In meiotic divisions of male flowers one large chromosome, behaving as a univalent, and a seemingly unequal pair were observed.

BALSAMINACEAE			
<i>Impatiens Holstei</i>		16	HEITZ, 1929a.

¹⁾ The behaviour of the reduction division of this species showed distinct irregularities especially in the heterotypic division. In homoeotypic division abnormalities were more seldom.

²⁾ An unequal pair of chromosomes was distinguishable in meiotic divisions of the male flowers.

³⁾ The chromosome complex is described as $7 + 2n$.

⁴⁾ An unequal pair of chromosomes was not always clearly distinguishable in meiotic divisions of male flowers.

¹⁾ Bivalents were regularly seen at diakinensis — lagging univalents being very few.

²⁾ Divisions were regular for the most part.

³⁾ A haploid flower was found on a shoot of a diploid plant which was lost.

⁴⁾ This plant especially resembled *N. atriplicifolia*.

⁵⁾ 4 to 8 monovalents or 2 to 3 trivalents might appear.

⁶⁾ This haploid arose in the F_2 generation from a varietal cross in which there was complete fertility. (Red Pear × Dwarf Peach).

⁷⁾ The first meiotic division was not an orderly procedure as 6 chromosomes might go to either pole or there might be random distribution.

⁸⁾ Occasional cells in the root-tips of the haploid possessed more than 12 chromosomes, 3 cells had 24 and 1 cell was found to have only 11.

¹⁾ One monosomic *alata* form occurred in a population of 80 plants resulting from controlled pollination with normal pollen.

²⁾ Of 57 plants only 2 showed 19 chromosomes.

³⁾ In a trisomic plant a single large spindle showed 19 chromosomes.

⁴⁾ Of 22 plants 4 showed 22, 25, 26 and 27 chromosomes.

⁵⁾ Though the other plants with additional chromosomes showed no marked alteration in external morphology the plant with 22 chromosomes was a dwarf and the one with 25 chromosomes was abnormal with misshapen flowers.

⁶⁾ The plant with 27 chromosomes showed a full triploid set.

⁷⁾ This haplont was one of 24 plants that grew from seedlings which had been

¹⁾ As the plant was identical with *N. tabacum purpurea* haploids except that it had white instead of carmine flowers it was concluded that this was a case of haploid merogony.

²⁾ Not infrequently fewer units than 35 were found and this was explained as the result of formation of polyvalent chromosomes.

³⁾ Out of 58 root-tip pieces only one was diploid, the rest all being haploid.

¹⁾ One triploid plant (2n = 12) appeared.²⁾ Two plants appeared to have 9 as the diploid number. In a large epidermal cell 14 chromosomes were found.³⁾ The F₁ plants were largely diploid, or triploid with a few trisomic plants.⁴⁾ The F₂ plants included about the same proportion of diploid and triploid plants but also disomics and trisomics 3n + 1, 3n + 1 + 1 as well as a few tetraploids and 7n plants.⁵⁾ MEDWEDEWA found the plant cells to have 2 large satellites, 2 small satellites or 1 large and 1 small satellite.

¹⁾ An unequal pair of chromosomes was distinguishable in meiotic divisions of male flowers of this form. Only somatic plates of the second form ($2n = 24$) were examined.

²⁾ According to BEADLE (1929) in sterile maize plants the two normal divisions of microsporogenesis were followed by further aberrant divisions until as many as 8 cells resulted, each with considerably less than the normal haploid number of chromosomes.

¹⁾ The variation in the number of bivalents in the embryo-sac-mother-cell was similar to that found in the pollen-mother-cell.

²⁾ In pollen-mother-cells, 0—5 bivalents were found whereas in the embryo-sac-mother-cell, 7 bivalents and 21 univalents occurred.

³⁾ Usually 7 pairs mated.

⁴⁾ Usually there were 11 bivalents and 7 univalents.

<i>Fritillaria imperialis</i>	24—6		DARLINGTON, 1929e.

¹⁾ The number was determined from a rough count of a few equatorial plates in the endosperm showing the triple fusion nucleus with ca. 72.

²⁾ Due to various arrangements of 12 chromosomes as 6 bivalents, 5 + 2₁, 4 + 4₁, 3 + 6₁, 2 + 8₁, 1 + 10₁, or 12₁ followed by division of some univalents, as many as 18 chromosomes have been found in microspores.

³⁾ Due to non distribution varying numbers of chromosomes were found in somatic cells, the highest number being 56.

⁴⁾ 16 Gemini were formed at diakinesis. At the heterotypic division no typical equatorial plate was formed and diads might be formed or homoeotypic division with a typical equatorial plate might follow.

<i>Bellevallia speciosa</i> G. WOR.	4	DELAUNAY, 1928.

¹⁾ NAGAO 1929 stated that this named variety was classified by some authors as some other species.

²⁾ Sometimes 1 to several univalents were among the trivalents so that 8, 9 or 10 chromosomal units may be counted in the nuclear plate. The chromosome numbers in the homoeotypic plates were 10 and 11 and 10 and 12.

³⁾ Sometimes univalent and bivalent chromosomes appeared with the trivalents.

¹⁾ KACHIDZE (1929b) found that there were 2 pairs of satellites in the homozygous and 1 pair in the heterozygous race.

²⁾ Generally there were no abnormalities in the meiotic prophase but occasionally one or 2 bivalents were loosely paired.
